November 15, 2016

I'm running out of paper, that's why I wrote my homework in a pdf file. Otherwise I will never use it because it took a lot of time...

## 1 Electronic heat capacity of a superconductor

(a) DOS of the superconductor is

$$\rho(E)dE = \int \frac{d^d k}{(2\pi)^d} \delta(E - E_k) dE = \int \frac{d^d k}{(2\pi)^d} \delta(\varepsilon - \varepsilon_k) d\varepsilon = \int \frac{d^d k}{(2\pi)^d} \delta(\varepsilon - \varepsilon_k) \frac{d\varepsilon}{dE} dE = \rho_0 \frac{d\varepsilon}{dE} dE$$

$$\text{where } E = E_F \pm \sqrt{\Delta^2 + (\varepsilon - E_F)^2}$$

$$\frac{dE}{d\varepsilon} = \pm \frac{\varepsilon - E_F}{\sqrt{\Delta^2 + (\varepsilon - E_F)^2}} = \frac{|\varepsilon - E_F|}{\sqrt{\Delta^2 + (\varepsilon - E_F)^2}} = \frac{\sqrt{(E - E_F)^2 - \Delta^2}}{|E - E_F|}, \quad |E - E_F| \geq \Delta$$

Therefore

$$\rho(E) = \rho_0 \frac{|E - E_F|}{\sqrt{(E - E_F)^2 - \Delta^2}}, \quad |E - E_F| \geq \Delta$$

$$\text{otherwise } \rho(E) = 0$$

(b) The DOS looks like

(c) Define  $E - E_F = x$ , total energy

$$U = 2 \int_{\Delta}^{\infty} (x + E_F) f(x) \rho(x) dx = 2 \int_{\Delta}^{\infty} (x + E_F) \frac{1}{e^{x/T} + 1} \rho_0 \frac{x}{\sqrt{x^2 - \Delta^2}}$$

When  $T \ll \Delta$ ,  $f(x) \simeq e^{-x/T}$ . Also assume  $\rho_0 \frac{x}{\sqrt{x^2 - \Delta^2}}$  remains constant as long as  $|x| \sim \Delta$  or  $e^{-x/T}$  is extremely small.

Therefore

$$U \simeq 2 \int_{\Delta}^{\infty} (x + E_F) e^{-x/T} \rho_0$$

Using integrals

$$\int_{\Delta}^{\infty} e^{-x/T} dx = T e^{-\Delta/T}$$

$$\int_{\Delta}^{\infty} x e^{-x/T} dx = T(\Delta + T) e^{-\Delta/T}$$

Then we have

$$U \simeq 2T(\Delta + T + E_F) e^{-\Delta/T} \rho_0$$

(d) The main contribution to electronic heat capacity comes from those density of states near the Fermi energy. We can then use the analytic result from (c)

$$C_e = \left(\frac{\partial U}{\partial T}\right)_{N,V} \simeq 2\left(\frac{(\Delta + E_F)\Delta}{T} + 2\Delta + E_F + 2T\right)e^{-\Delta/T}\rho_0$$

## 2 Calculating the Sommerfeld expansion for a 1-d metal

- (a) If the band is half fill, the electronic density in  $k$  space is  $g\frac{a}{2\pi}$ ,  $k \in (-\frac{\pi}{2a}, \frac{\pi}{2a})$ , where  $g$  is the spin degeneracy,  $g = 2$  for electrons

Therefore, the electronic density in  $x$  space is

$$\int_{-\frac{\pi}{2a}}^{\frac{\pi}{2a}} g\frac{a}{2\pi} e^{-ikx} dk = \frac{g}{2} \text{sinc}\left(\frac{\pi x}{2a}\right), \quad x \in \left(-\frac{a}{2}, \frac{a}{2}\right), \quad \text{where } \text{sinc}(y) = \frac{\sin(y)}{y}$$

- (b) Fermi energy of system corresponds to the highest  $\varepsilon_k$ . Suppose the number density of the electron per unit cell is  $n = \frac{N}{a}$ , the band will fill up to  $k_F = \pm \frac{1}{g} \frac{2\pi}{a} n$  (Note  $n$  is also the filling factor of the band). Therefore,

$$E_F = \mu = -t \cos(ka) \big|_{k=\pm \frac{1}{g} \frac{2\pi}{a} n} = -t \cos\left(\frac{1}{g} 2\pi n\right)$$

- (c) Density of states

$$\rho(\varepsilon) d\varepsilon = \int \frac{dk}{2\pi} \delta(\varepsilon - \varepsilon_k) d\varepsilon = \int \frac{dk}{2\pi} \delta(k - k_\varepsilon) \frac{dk}{d\varepsilon} d\varepsilon = g \frac{a}{2\pi} \frac{1}{a t \sin(ka)} d\varepsilon = \frac{g}{2\pi} \frac{1}{\sqrt{t^2 - \varepsilon^2}} d\varepsilon, \quad \varepsilon \in (-t, t)$$

- (d) Total energy in the band (in a unit cell)

$$U = \int_{-t}^t \varepsilon f(\varepsilon) \rho(\varepsilon) d\varepsilon = \int_{-t}^t \frac{g}{2\pi} \varepsilon \frac{1}{\sqrt{t^2 - \varepsilon^2}} \frac{1}{e^{(\varepsilon - \mu)/T} + 1} d\varepsilon$$

Using Sommerfeld expansion

$$\int_{-t}^t h(\varepsilon) \frac{1}{e^{(\varepsilon - \mu)/T} + 1} d\varepsilon = \int_{-t}^{\mu} h(\varepsilon) d\varepsilon + \int_{-t}^{\mu} h(\varepsilon) \left( \frac{1}{e^{(\varepsilon - \mu)/T} + 1} - 1 \right) d\varepsilon + \int_{\mu}^t h(\varepsilon) \frac{1}{e^{(\varepsilon - \mu)/T} + 1} d\varepsilon = \int_{-t}^{\mu} h(\varepsilon) d\varepsilon -$$

$$\int_{-t}^{\mu} h(\varepsilon) \frac{1}{e^{-(\varepsilon - \mu)/T} + 1} d\varepsilon + \int_{\mu}^t h(\varepsilon) \frac{1}{e^{(\varepsilon - \mu)/T} + 1} d\varepsilon$$

Substitute  $(\varepsilon - \mu)$  to  $-(\varepsilon - \mu)$  in the second integration, and let the upper limits of the integration  $t + \mu, t - \mu$  be  $\infty$

$$\int_{-t}^{\mu} h(\varepsilon) d\varepsilon + \int_0^{\infty} (h(\mu + \varepsilon) - h(\mu - \varepsilon)) \frac{1}{e^{\varepsilon/T} + 1} d\varepsilon$$

where

$$h(\mu + \varepsilon) - h(\mu - \varepsilon) = 2 \sum_{n=0}^{\infty} \frac{1}{(2n+1)!} h^{(2n+1)}(\mu) \varepsilon^{2n+1}$$

Therefore

$$\int_{-t}^{\mu} h(\varepsilon) d\varepsilon + 2 \sum_{n=0}^{\infty} \frac{1}{(2n+1)!} h^{(2n+1)}(\mu) \int_0^{\infty} \frac{x^{2n+1}}{e^x + 1} dx T^{2n+2}$$

Up to  $T^4$ , we have

$$U = \frac{g}{2\pi} \left\{ -\sqrt{t^2 - \mu^2} + \frac{\pi^2}{6} \frac{t^2}{\sqrt{t^2 - \mu^2}^3} T^2 + \frac{7\pi^4}{360} \frac{3t^2\mu}{\sqrt{t^2 - \mu^2}^5} T^4 \right\}$$

- (e) Up to  $T^3$ , the heat capacity of the electron gas is

$$C_e = \left( \frac{\partial U}{\partial T} \right)_{V,N} = \frac{g}{2\pi} \left\{ \frac{\pi^2}{3} \frac{t^2}{\sqrt{t^2 - \mu^2}^3} T + \frac{7\pi^4}{30} \frac{t^2\mu}{\sqrt{t^2 - \mu^2}^5} T^3 \right\}$$

- (f) If chemical potential  $\mu$  is held constant at  $E_F$ , the number of particles in a unit cell is

$$N = \int_{-t}^t f(\varepsilon) \rho(\varepsilon) d\varepsilon = \int_{-t}^t \frac{g}{2\pi} \frac{1}{\sqrt{t^2 - \varepsilon^2}} \frac{1}{e^{(\varepsilon - \mu)/T} + 1} d\varepsilon$$

Using Sommerfeld expansion, we have

$$N = \frac{g}{2\pi} \left\{ \arctan\left(\frac{3t^2\mu}{\sqrt{t^2 - \mu^2}}\right) + \frac{\pi}{2} \right\} + 2 \sum_{n=0}^{\infty} \frac{1}{(2n+1)!} \rho^{(2n+1)}(\mu) \int_0^{\infty} \frac{x^{2n+1}}{e^x + 1} dx T^{2n+2}$$

For example, up to  $T^4$

$$N = \frac{g}{2\pi} \left\{ \arctan\left(\frac{3t^2\mu}{\sqrt{t^2 - \mu^2}}\right) + \frac{\pi}{2} + \frac{\pi^2}{6} \frac{\mu}{\sqrt{t^2 - \mu^2}^3} T^2 + \frac{7\pi^4}{360} \frac{t^2 + 2\mu^2}{\sqrt{t^2 - \mu^2}^5} T^4 \right\}$$

Consistency check: if  $\mu = 0$ , ie, half filled, then to the 0th order,  $N = \frac{g}{4}$ , number density  $n = g \frac{a}{4}$ , Fermi vector  $k_F = \pm \frac{1}{g} \frac{2\pi}{a} n = \pm \frac{\pi}{2}$ ,  $\mu = 0$

### 3 Adiabatic expansion

- (a) Proof.

$$\text{RHS} = \left( \frac{\partial P}{\partial V} \right)_{S,N} = \left( \frac{\partial P}{\partial V} \right)_{T,N} + \left( \frac{\partial P}{\partial T} \right)_{V,N} \left( \frac{\partial T}{\partial V} \right)_{S,N} = \left( \frac{\partial P}{\partial V} \right)_{T,N} \left\{ 1 + \frac{(\frac{\partial P}{\partial T})_{V,N} (\frac{\partial T}{\partial V})_{S,N}}{(\frac{\partial P}{\partial V})_{T,N}} \right\}$$

where

$$\frac{(\frac{\partial P}{\partial T})_{V,N} (\frac{\partial T}{\partial V})_{S,N}}{(\frac{\partial P}{\partial V})_{T,N}} = - \left( \frac{\partial V}{\partial T} \right)_{P,N} \left( \frac{\partial T}{\partial V} \right)_{S,N} = \left( \frac{\partial V}{\partial T} \right)_{P,N} \left( \frac{\partial S}{\partial T} \right)_{V,N}$$

Therefore

$$\text{RHS} = \left( \frac{\partial P}{\partial V} \right)_{T,N} \left\{ 1 + \left( \frac{\partial V}{\partial T} \right)_{P,N} \left( \frac{\partial S}{\partial T} \right)_{V,N} \right\} = \left( \frac{\partial P}{\partial V} \right)_{T,N} \left\{ \left( \frac{\partial S}{\partial T} \right)_{V,N} + \left( \frac{\partial V}{\partial T} \right)_{P,N} \left( \frac{\partial S}{\partial V} \right)_{T,N} \right\} = \left( \frac{\partial P}{\partial V} \right)_{T,N} \left( \frac{\partial S}{\partial T} \right)_{V,N} \left( \frac{\partial S}{\partial V} \right)_{T,N} =$$

$$\frac{C_P}{C_V} \left( \frac{\partial P}{\partial V} \right)_{T,N} = \frac{C_P}{C_V \left( \frac{\partial V}{\partial P} \right)_{T,N}} = - \frac{C_P}{C_V V \kappa_T} = \text{LHS}$$

- (b) For an ideal gas,  $PV = NT$ ,  $\left( \frac{\partial V}{\partial P} \right)_{T,N} = -\frac{NT}{P^2}$ ,  $\frac{C_P}{C_V} = \gamma$  is a constant  
Then we have

$$\begin{aligned}(\frac{\partial P}{\partial V})_{S,N} &= -\frac{\gamma P^2}{NT} = -\frac{\gamma P}{V} \\(\frac{\partial P}{\partial T})_{S,N} &= -\gamma(\frac{\partial V}{\partial T})_{S,N} \\(PV^\gamma)_{S,N} &= \text{constant}\end{aligned}$$

- (c) For monoatomic ideal gas in  $d$  dimensions

$$U = U_{\text{kinetic}} = \frac{1}{2}dNT \text{ (equipartition theorem)}$$

$$C_V = (\frac{\partial U}{\partial T})_{V,N} = \frac{1}{2}dN$$

$$C_P = C_V + N = (\frac{1}{2}d + 1)N \text{ (ideal gas law)}$$

$$\text{Then } \gamma_{\text{mono}} = 1 + \frac{2}{d}$$

For diatomic ideal gas in  $d$  dimensions (with no vibrational excitations)

$$U = U_{\text{kinetic}} + U_{\text{rotational}}$$

Assume the rotation is confined to  $3d$  and due to two rotation axes. The partition function for a single molecule is given in PS5, which is

$$Z_1 = \frac{8\pi^2 IT}{h^2}$$

where  $I$  is the moment of inertia about the center axis perpendicular to the line connecting the two atoms

$$\text{Free energy } F = -T \ln(Z_N) = -NT \{ \ln(\frac{8\pi^2 IT}{h^2 N}) + 1 \}$$

$$\text{Entropy } S = -(\frac{\partial F}{\partial T})_{N,V} = N \{ \ln(\frac{8\pi^2 IT}{h^2 N}) + 2 \}$$

$$U_{\text{rotational}} = F + TS = NT \text{ (not suprising because of the equipartition theorem)}$$

$$C_V = (\frac{\partial U}{\partial T})_{V,N} = (\frac{1}{2}d + 1)N$$

$$C_P = C_V + N = (\frac{1}{2}d + 2)N$$

$$\text{Then } \gamma_{\text{di}} = 1 + \frac{2}{d+2}$$

## 4 White dwarves

- (a) For non-relativistic free electrons, we have (derived in class)

$$E_F = \frac{\hbar^2}{2m} (3\pi^2 \frac{N}{V})^{\frac{2}{3}} \text{ (include } g = 2 \text{ for electrons)}$$

where  $N = \frac{2M}{m_{He}}$ ,  $V = \frac{4}{3}\pi R^3$ ,  $m_{He}$  is the atomic mass of helium (ignore the mass contribution from the electrons and all electrons are not bound to the atom, thus each nuclei will give two electrons)

$$\text{Therefore } E_F = \frac{\hbar^2}{2m} (\frac{9}{4} \frac{\pi}{R^3} \frac{2M}{m_{He}})^{\frac{2}{3}}$$

- (b) Total energy of the electron gas is (derived in class)

$$U_e = \frac{3}{5} E_F N = \frac{3}{5} \frac{\hbar^2}{2m} (\frac{3\pi^2}{V})^{\frac{2}{3}} N^{\frac{5}{3}} = \frac{3}{5} \frac{\hbar^2}{2m} (\frac{9}{4} \frac{\pi}{R^3})^{\frac{2}{3}} (\frac{2M}{m_{He}})^{\frac{5}{3}}$$

- (c) The gravitational potential between two objects with mass  $m_1$  and  $m_2$  is

$$U(m_1, m_2) = -\frac{Gm_1 m_2}{r}$$

Then consider piling up a sphere with radius  $R$  and density  $\rho$ , the work done on this process is

$$W = -\int_0^R \frac{Gm(r)dm}{r} = -\int_0^R \frac{G \frac{4}{3}\pi r^3 \rho}{r} 4\pi r^2 \rho dr = -\int_0^R G \frac{4}{3}\pi^2 \rho^2 r^4 dr = -G \frac{16}{15} \pi^2 \rho^2 R^5$$

$$\text{Using } M = \frac{4}{3}\pi R^3 \rho, W = -\frac{3}{5} \frac{GM^2}{R}$$

Therefore the gravitational energy of the star is

$$U_g = -\frac{3}{5} \frac{GM^2}{R}$$

- (d) Total energy of the star

$$U(R) = U_e + U_g = \frac{3}{5} \frac{\hbar^2}{2m} (\frac{9}{4}\pi)^{\frac{2}{3}} (\frac{2M}{m_{He}})^{\frac{5}{3}} \frac{1}{R^2} - \frac{3}{5} \frac{GM^2}{R} = \frac{A}{R^2} - \frac{B}{R}$$

In equilibrium

$$\frac{dU}{dR} = 0, \frac{2A}{R^3} = \frac{B}{R^2}, R = \frac{2A}{B}$$

Plug in the detailed numbers, we have

$$A = 1.941 \times 10^{56} \text{ J} \cdot \text{m}^2 (\frac{M}{M_S})^{\frac{5}{3}}$$

$$B = 4.004 \times 10^{49} \text{ J} \cdot \text{m} (\frac{M}{M_S})^2$$

where  $M_S$  is the mass of the sun

$$\text{Then } R = 9.695 \times 10^6 \text{ m} (\frac{M}{M_S})^{-\frac{1}{3}}$$

The Fermi energy is

$$E_F = \frac{5}{3} \frac{U_e}{N} = \frac{5}{3} \frac{A}{R^2 N} = 68.67 \text{keV} \left( \frac{M}{M_S} \right)^{\frac{4}{3}}$$

whereas the rest energy of the electron is 511keV,  $E_F$  is 13.4% of the rest energy when  $M = M_S$

The electrons can't be treated non-relativistically

- (e) For ultra-relativistic electrons, the Fermi momentum is the same as the non-relativistic case

$$p_F = \hbar(3\pi^2 \frac{N}{V})^{\frac{1}{3}} \quad (\text{include } g = 2 \text{ for electrons})$$

In ultra-relativistic limit

$$E_F = p_F c = \hbar c(3\pi^2 \frac{N}{V})^{\frac{1}{3}}$$

Total energy of the electron gas is

$$U_e = \frac{3}{4} E_F N = \frac{3}{4} \hbar c \left( \frac{3\pi^2}{V} \right)^{\frac{1}{3}} N^{\frac{4}{3}} = \frac{3}{4} \hbar c \left( \frac{9}{4} \frac{\pi}{R^3} \right)^{\frac{1}{3}} \left( \frac{2M}{m_{He}} \right)^{\frac{4}{3}}$$

(Sorry I didn't derive it... Just copied from wiki. It's too late and the derivation is trivial...)

Total energy of the star is

$$U(R) = U_e + U_g = \frac{3}{4} \hbar c \left( \frac{9}{4} \pi \right)^{\frac{1}{3}} \left( \frac{2M}{m_{He}} \right)^{\frac{4}{3}} \frac{1}{R} - \frac{3}{5} \frac{GM^2}{R} = \frac{C}{R} - \frac{B}{R}$$

where

$$C = 9.262 \times 10^{49} \text{J} \cdot \text{m} \left( \frac{M}{M_S} \right)^{\frac{4}{3}}$$

$$B = 4.004 \times 10^{49} \text{J} \cdot \text{m} \left( \frac{M}{M_S} \right)^2 \text{ is the same as before}$$

- (f) For the star to be stable,  $\frac{dU}{dR} = -\frac{C-B}{R^2} < 0$ , i.e.,

$$9.262 \left( \frac{M}{M_S} \right)^{\frac{4}{3}} > 4.004 \left( \frac{M}{M_S} \right)^2$$

$$\frac{M}{M_S} < \left( \frac{9.262}{4.004} \right)^{\frac{3}{2}} \simeq 3.52$$

This is a strange number... which should be around 1.4
